Complex Analysis MAT656.

José Pabón

May, 2020

These problems are from the pdf received from Prof. Blackmore. The course textbook is Ablowitz and Fokas [1].

1 August 2018 Problem 4. - Prove the isolated zero theorem.

1.1 Proof from Ablowitz and Fokas:

f(z) analytic at z_0 implies the function has a Taylor series expression about $z = z_0$. If it has a zero of order n, we have that:

$$f(z) = (z - z_0)^n g(z).$$

With g(z) analytic and having a Taylor series at $z = z_0$ and $g(z_0) \neq 0$. There must exist a maximum integer n, otherwise f(z) would be identically zero in a neighborhood of z_0 and must vanish everywhere in our domain. This is a result from previous theorems including this theorem (3.2.6 in the text):

Theorem - If f(z), g(z), are analytic in common domain D, if f(z), g(z) coincide in some subportion $D' \subset D$, then $f(z) = g(z) \forall z \in D$.

Given g(z) is analytic, we have that:

 $\exists \ \epsilon > 0, |g(z) - g(z_0)| < \epsilon \text{ whenever z is in a neighborhood of } z_0, 0 < |z - z_0| < \delta.$

Thus, g(z) can be made arbitrarily as close to $g(z_0)$ as desired, thus:

$$g(z) \neq 0, f(z) \neq 0$$
, in this neighborhood.

 \therefore if f is a nonconstant analytic function in a domain $D \subset C$, then if $f(z_0) = 0$ for $z_0 \in D$, there exists an $\epsilon > 0$ such that f is not zero for any point of the punctured neighborhood \checkmark .

•

2 Conclusion

Thank you to Prof. Blackmore for his instruction, lectures and office hours effort. I look forward to any feedback and learning more of the material in this course and beyond.
